

Experiment No : 5

Aim : Implement Genetics /> Hill Climbing in python and observe its working & results.

Theory :

- Hill Climbing is a local search algorithm.
- Hill Climbing is simply a combination of depth first search with generate and test, where a 'feedback' is used here to decide on the direction of motion in the search space.
- Hill climbing technique is used widely in AI, to solve computationally hard problems, which has multiple possible solutions.

- In the DFS, the test function will accept state to reject a solution. But in Hill climbing the test function is provided with a heuristic function which provides an estimate of how close a given state is to goal state.
- In hill climbing, each state is provided with the additional information needed to find the solution, i.e. the heuristic value.
- The algorithm is memory efficient since it does not maintain the complete search tree.
- For e.g. if you want to find a mall from our current location.
- There are n possible paths with different directions to reach the mall if the heuristic function will just give you the distance of each path which is reaching to the mall,

so that it becomes very simple and time efficient for you to reach to the solution.

Algorithm :

- 1) Evaluate the initial state. If it is a goal state, then return and quit; otherwise make it a current state and go to step 2.
- 2) Loop until a solution is found or there are no new operators left to be applied.
 - a) Select and apply a new operator.
 - b) Evaluate the new state. If it is a goal state, then return and quit; if it is better than current state, then make it a new current state.
 - c) If it is not better than the current state, then continue the loop in a loop, going to step 2.

Genetic Algorithm

- ⇒ GAs are adaptive heuristic search algorithms based on the evolutionary ideas of natural selection and genetics.
- As they represent an intelligent exploitation of a random search used to solve optimization problems.
- Although randomized, GAs are by no means a random; instead they exploit historical information to direct the search.

for better performance within the search space and a combination of both.

- The basic techniques of the GAs are designed to simulate processes in natural systems necessary for evolution, especially those of following the principles of "survival of the fittest" laid down by Charles Darwin.
- For e.g., 8 bit arrangements.

Parent's chromosomes are as follows:

| Chromosome A | 1 | 3 | 3 | 2 | 6 | 4 | 7 | 9 | 8 |
|--------------|---|---|---|---|---|---|---|---|---|
| Chromosome B | 8 | 5 | 6 | 7 | 2 | 3 | 1 | 4 | 9 |

Let's consider the example of pair chromosomes encoded using permutation encoding technique and are undergoing the complete process of GA.

Assuming that they are selected using rank selection method and will be applied, arithmetic crossover and value encoding mutation techniques.

Child chromosome after arithmetic crossover i.e. adding bits of both chromosomes.
 Child chromosome:

| Chromosome C | 9 | 0 | 9 | 9 | 8 | 7 | 8 | 3 | 7 |
|--------------|---|---|---|---|---|---|---|---|---|
|--------------|---|---|---|---|---|---|---|---|---|

- After applying value encoding mutation i.e. adding or subtraction a small value to selected values e.g. π instead of π to 3rd and 4th bit after performing crossover it leads to better fitness, mutation and crossover.
 - Child chromosome is produced from parents which has best fitness value.
- | | |
|--------------|--------------------|
| Chromosome C | 90 8.8 8.2 8.3 8.7 |
|--------------|--------------------|

It can be observed that the child produced is much better than both parents.

| | | |
|----------|---------------------|--------------|
| Parent A | 8.0 8.2 8.8 8.2 8.1 | A 3 mutation |
| Parent B | 9.0 9.2 9.8 9.2 9.8 | B 3 mutation |

producing offspring with fitness value 9.0 which is better than both parents. Offspring with fitness value 9.0 is produced by mutation. Fitness value 9.0 is better than parents which have fitness value 8.8 and 9.2 respectively. Offspring with fitness value 9.0 is produced by mutation. Fitness value 9.0 is better than parents which have fitness value 8.8 and 9.2 respectively.

These combinations are the improvements made to the population that is studied with respect to improvements made.

| | | |
|---------------------|---------------------|---------------------|
| 8.8 8.1 8.0 8.0 8.1 | 9.0 9.2 9.8 9.2 9.8 | 9.0 9.2 9.8 9.2 9.8 |
|---------------------|---------------------|---------------------|

Code: (Genetics*)

```

import random

def equation(a, b, c, d):
    return a + 2 * b + 17 * c + 14 * d
